# Polysemous words

I  
ate  
an  
apple  
in  
the  
morning  
for  
breakfast

$V1(d,1)$

I  
bought  
an  
apple  
series  
13  
with  
new  
updates

$V3(d,1)$

---

# Motivation

Like unisense vectors, sense-specific vectors should be closely aligned to words in that sense. (Chen et al., 2014; Huang et al., 2012; Le and Mikolov, 2014; Neelakantan et al., 2015)

---

# Approach

- This model is built on top of Gensim word2vec
  - The vector embeddings of word2vec are uni-sense, we will call them as base embeddings
  - Our aim is to construct contextual embeddings, which can be constructed using the base embeddings
-

---

# How to construct Contextual Embeddings?

Example:

- 1) I was sitting by the side of the River **bank**.
- 2) I need to withdraw my savings from the **bank**.

Notice, how the context changes the meaning of the word in the above examples.

---

# Contextual Embeddings

$\text{bank1} = W[\text{sitting}, \text{bank}] * \text{base\_vector}(\text{sitting}) + W[\text{side}, \text{bank}] * \text{base\_vector}(\text{side}) + W[\text{River}, \text{bank}] * \text{base\_vector}(\text{river})$

and,

$\text{bank2} = W[\text{need}, \text{bank}] * \text{base\_vector}(\text{need}) + W[\text{withdraw}, \text{bank}] * \text{base\_vector}(\text{withdraw}) + W[\text{savings}, \text{bank}] * \text{base\_vector}(\text{savings})$

Here,

$W[\text{context\_word}, \text{target\_word}]$  defines the relevance of that context word.

$W = 1$  , means high relevance

$W=0$ , means no relevance

---

---

# Visualizing contextual embedding

$$\text{Target} = w1^* \begin{array}{c} \text{teal bar} \\ \text{base\_vector1} \end{array} + w2^* \begin{array}{c} \text{blue bar} \\ \text{base\_vector2} \end{array} + w3^* \begin{array}{c} \text{orange bar} \\ \text{base\_vector3} \end{array} + \dots$$

The diagram illustrates the linear combination of base vectors to form a target. It shows three vertical bars: a teal bar labeled 'base\_vector1', a blue bar labeled 'base\_vector2', and an orange bar labeled 'base\_vector3'. Each bar is preceded by a weight term:  $w1^*$ ,  $w2^*$ , and  $w3^*$  respectively. The bars are separated by plus signs, and the sequence ends with an ellipsis ( $\dots$ ) to indicate further terms in the sum.

---

---

## But What is W?

- A Matrix  $W$  of  $V \times V$  dimensions where  $V$  is the total vocabulary of the selected corpus. In the paper above,  $W[i,j]$  is defined as,

$W[i,j]$  = co-occurrence of words  $i$  and  $j$  / (freq.\_of\_word\_  $i$  \* freq\_of\_word\_  $j$ )

$$W[i,j] = \frac{f(i,j)}{f(i) * f(j)}$$

- Equations apart,  $W$  is a relevance matrix that tells how relevant a context is for a target word.
  - In example 1, **river** is more **relevant** to **bank** than other context words.
-

---

# Words with most relevant context

context	largest norm words
eye	retina, ophthalmology, eye, sockets
keyboard	keyboard, layouts, harpsichord, sonata
run	yd, inning, td, rb
ball	fumbled, lucille, ball, wrecking
chips	chips, potato, pentium, chip

---

---

## So to sum up!

- contextual embedding of a word as a linear combination of its contexts.(Yifan Sun et al.)
  - The target embedding is the embedding of the word in the context of the sentence
-

---

# Project details

- Python programming language
  - Base model : Gensim word2vec
  - Trained on wiki-corpus
  - Evaluation : SCWS(Stanford's Contextual Word Similarities)
  - Source(dataset/test set) : [Richard Socher - Improving Word Representations Via Global Context And Multiple Word Prototypes.](#)
  - My Project available on :  
[https://github.com/SagarDollin/unsupervised\\_WSD\\_on\\_top\\_of\\_word2vec](https://github.com/SagarDollin/unsupervised_WSD_on_top_of_word2vec)
-

---

# Evaluation and results

- The model was evaluated on **SCWS** test set.
  - This is a test set that has two (word,context) pairs and have a similarity measure between two words annotated by human readers, based on the context.
  - **Result: The predicted similarity scores (cosine similarity) and ground-truth ranking have an Average Difference = 0.27 (Inaccuracy measure)**
  - **Accuracy measure =  $1 - 0.27 = 0.73$  (approx)**
-

# Compare the evaluation results with original paper (Yifan Sun et al.)

- Note that, here in the image, **our method** refers to the method used by Yifan sun et al
- In the image SCWS scores are in Spearman correlation metric. I used accuracy measure :  $(1 - (\text{avg\_diff}))$
- If we want to compare Accuracies, we can compare the accuracy I got for SCWS and the Accuracy the original paper's authors got for CWS.
- My accuracy is 0.73 i.e., 73%(SCWS) where as their accuracy is (89-90%) for CWS

Embeddings	dim.	WCR						CWS		SCWS	WSC

# W

	Potato	chip	Pentium
Potato	1	0.4	0
chip	0.4	1	0.2
Pentium	0	0.2	1
Glass	0	0	0

Problem?

The matrix occupies too much space on memory.

The matrix is generally sparse

---

---

# Solution

Take the dot products of  $i$  and  $j$  word embeddings to get a relevancy score

$$= w(i,j)$$

# The idea is similar to attention?

The relevancy scores are just the attention scores.

In our case the query is the target word embedding and we calculate score for each embedding in the context using this query.

Input	Thinking	Machines
Embedding	$x_1$ 	$x_2$ 
Queries	$q_1$ 	$q_2$ 
Keys	$k_1$ 	$k_2$ 
Values	$v_1$ 	$v_2$ 
Score	$q_1 \cdot k_1 = 112$	$q_1 \cdot k_2 = 96$
Divide by 8 ( $\sqrt{d_k}$ )	14	12
Softmax	0.88	0.12

This softmax score determines how much each word will be expressed at this position. Clearly the word at this position will have the highest softmax score, but sometimes it's useful to attend to another word that is relevant to the current word.
